

How Inflation Can Be an Opportunity for Active Fixed Income Investors

There are ways for active managers to generate positive returns from rising – and falling – inflation. The key is to understand the different risk premia that combine to make up government bond yields and how to use the relevant tools to take advantage of them.

Inflation is one of the key risks that investors in fixed income want to be paid to accept. And, like any other risk, inflation can also present opportunities. By selecting the appropriate instrument, investors may be able to generate positive returns from rising and falling inflation expectations, and from realized inflation that is higher or lower than expected by the market. The key questions investors need to answer are:

- What is currently priced in by the market relative to their own fundamental expectations – in other words: are current risk premia over- or under-compensating actual inflation risks?
- How will inflation expectations evolve over the period in question, and what are the most likely implications for the economy and central bank policy?

To answer these questions and help active fixed income investors, consider the different risk premia represented by government bond yields.

Breaking Down Government Bond Yields into Components of Risk Premia

For active fixed income investors, two factors determine total return over their holding period: 1) Carry, defined as income from interest or coupon payments from the bond or derivative (adjusted for accrued interest), and 2) price changes.

A range of factors influence bond yields and the shape of yield curves. To understand these effects, it is helpful to decompose the yield on a bond into the various components of risk premia.

When considering the yield of nominal government bonds, there are four key components to consider:¹

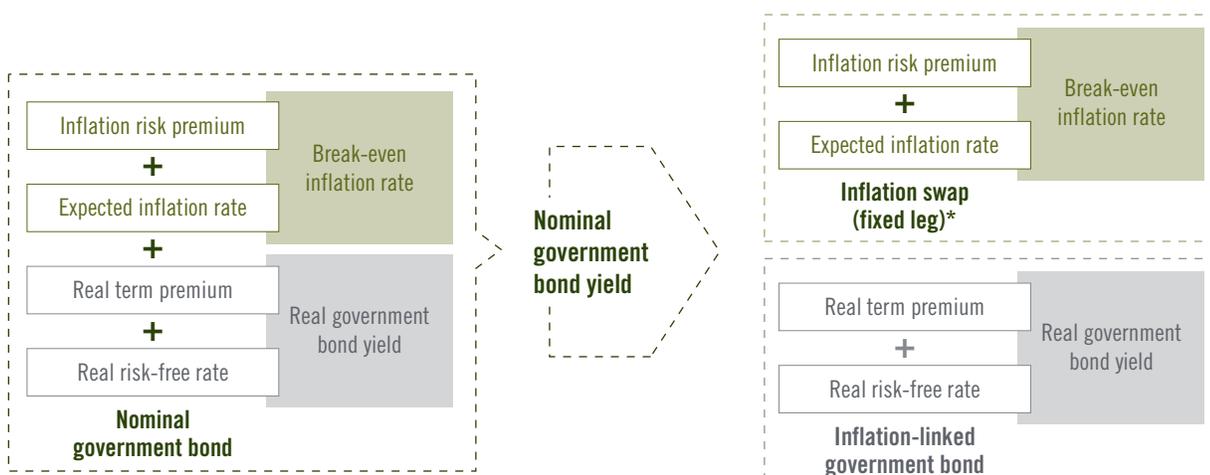

1 Real risk-free rate	2 Real term premium	3 Expected inflation rate	4 Inflation risk premium
The remuneration for saving money rather than spending it. This rate reflects expectations about economic growth and monetary policy.	The extra yield investors demand on longer-dated bonds to compensate them for unexpected changes in economic growth or monetary policy. Unfortunately, the term premium is not directly observable. One needs to model how much of the long-term yield represents expectations of the future path of short-term rates and how much reflects the term premium (i.e., the residual of the model).	Market participants' expectation of the average annual rate of inflation, i.e., the change in the underlying price index.	The compensation for unexpected inflation volatility. Think of this as an insurance premium against unexpected moves. ²
The sum of the real risk-free rate and the real term premium is the real yield – coupon income, expressed as a yield on the bond's price, after adjusting for inflation.		The sum of the expected inflation rate and the inflation risk premium is commonly referred to as the "break-even inflation rate." This is the average inflation rate over a set period, such that an investor would achieve the same return by either: a) using derivatives to lock in the average inflation rate based on current market expectations at the beginning of the transaction, or b) choosing to receive the actual rate of inflation as a variable cash flow for the period of the transaction.	

¹For simplicity, we are looking at "default risk-free" government bonds here. For corporate bonds or any other issuer at risk of potential default, a credit risk premium and a liquidity premium must be added. ²This premium is also difficult to observe directly – results vary across markets and models used.

Changes in expectations of how the four components of risk premia will evolve determine the direction for nominal government bond yields. However, there can be offsetting effects where, for example, the real risk-free rate decreases while inflation expectations increase. In this case, the individual effects offset each other at the level of nominal yields.

Taken together, the four components – expressed as the real (government bond) yield plus the break-even inflation rate – make up the nominal government bond yield, as illustrated by the chart below:

DECONSTRUCTING RISK PREMIA IN NOMINAL GOVERNMENT BOND YIELDS

*An inflation swap is a contract used to transfer inflation risk from one party to another through an exchange of fixed cash flows. In an inflation swap, one party pays a fixed rate cash flow on a notional principal amount while the other party pays a floating rate linked to an inflation index, such as the Consumer Price Index (CPI). Each cash flow comprises one leg of the swap.

Turning Inflation Expectations into Active Positions to Generate Potential Alpha

Once we have analyzed the economic fundamental and technical backdrops, identified the current levels of these four risk premia components, and formed a view on how we think they will change over a given investment horizon, we need to transform this view into active positions. Depending on the mandate, these can either be absolute or relative to a benchmark.

Each of these components can be traded separately, using individual instruments or combinations of them. An active fixed income manager can thus either take positions on nominal government bond yields, or on one or several of their risk premia, to generate returns.

Positions on **real government bond yields** can be taken directly using inflation-linked bonds. Most major economies have issued inflation-linked bonds with a wide range of maturities, generating real yield curves. As certain funds/mandates are not allowed to short physical bonds, a direct position towards rising real government bond yields requires derivatives. A short position in inflation-linked bonds can be replicated by going short the nominal government bond future plus an inflation swap where the investor receives the fixed leg (i.e., the break-even inflation rate) and pays the floating leg (i.e., realized inflation).

Although **real term premia** are not directly observable, positions on expected changes in real term premia can be taken via curve trades, where over- and underweights or long and short positions are taken on different parts of the yield curve (i.e., different maturities).

The **break-even inflation rate** is the difference in yield between a nominal and an inflation-linked bond with the same issuer and maturity. Positions on break-even inflation rate changes can either be relative – by simply replacing nominal with inflation-linked bonds in a portfolio or vice versa – or outright via inflation swaps.

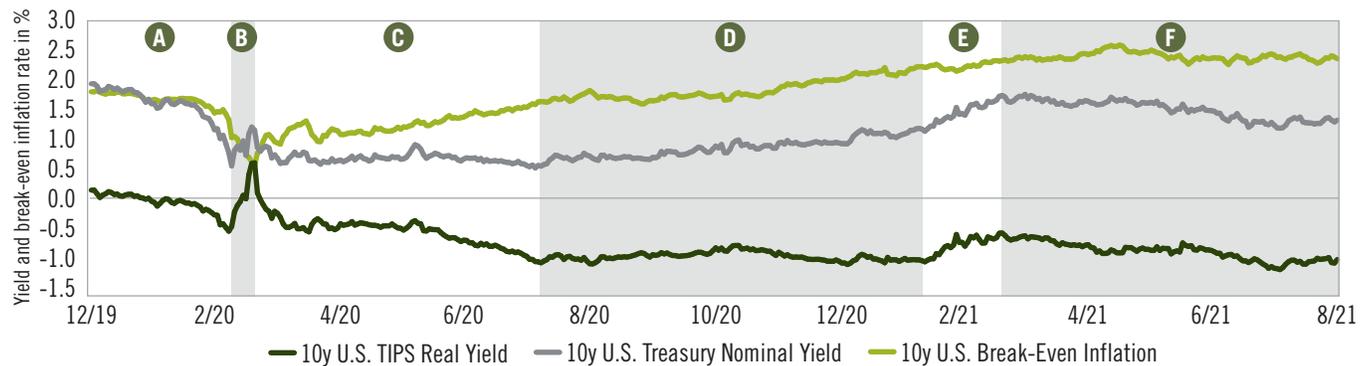

Options on inflation (inflation caps and floors) can be used to help hedge out the risk of an unexpected jump (or fall) in inflation. The option price is a measure for the **inflation risk premium**. Option markets can provide useful information on risk tolerance and market expectations, for example what it costs to hedge against the risk of deflation (i.e., negative inflation via inflation floors with a strike at 0%).

Real World Positioning Examples

Consider the behavior of long-term U.S. government bond yields over the past 18 months to see how active investors could have generated alpha from changes in inflation, or risk premia more generally, during this period.

The following chart shows the development of nominal 10-year U.S. Treasury yields, 10-year U.S. Treasury inflation-protected security (or TIPS) real yields since the beginning of 2020, and the difference between the two, the 10-year U.S. break-even inflation rate. The chart is divided into six distinct periods, where the start of each period is marked by a change in trend of one or more components, requiring changes to active positioning. The table that follows highlights market drivers that prevailed in each of those periods, and which instruments and positions would have generated alpha.

10 YEAR U.S. GOVERNMENT BOND YIELDS (REAL AND NOMINAL) AND BREAK-EVEN INFLATION

MARKET MOVEMENTS AND CORRESPONDING POSITIONING OPTIONS TO GENERATE ALPHA

Periods	Yield Changes	Market Drivers	Instruments and Positioning
A 01/01/20- 03/06/20	Real Yield ↓ Nominal Yield ↓ B/E Inflation ↓	From the second half of February, as growth concerns rose, a flight to “safe-haven” assets led to a collapse of nominal yields and breakevens (as real yields decreased less than nominal yields).	<ul style="list-style-type: none"> ■ Long nominal government bonds ■ Short inflation via inflation swaps (paying actual inflation, receiving the fixed leg) ■ In relative terms: overweight nominal vs. inflation-linked bonds.
B 03/07/20- 03/19/20	Real Yield ↑ Nominal Yield ↑ B/E Inflation ↓	At the peak of the crisis, investors needed to generate liquidity as quickly as possible, selling the most (and only) liquid parts of their portfolios: government bonds. Real yields rose sharply (much more than nominal yields since TIPS are less liquid and costlier for market makers to hold than nominal government bonds) and breakevens collapsed further.	<ul style="list-style-type: none"> ■ Short nominal government bond futures ■ Short inflation via inflation swaps (paying actual inflation, receiving the fixed leg) ■ In relative terms: overweight nominal vs. inflation-linked bonds.
C 03/20/20- 08/06/20	Real Yield ↓ Nominal Yield → B/E Inflation ↑	Central banks’ liquidity injections and enormous QE program announcements calmed markets. Real yields moved back to mid-March levels and then decreased further over the summer towards their low point in early August. Nominal yields decreased only slightly and break-evens rose.	<ul style="list-style-type: none"> ■ Long inflation-linked bonds ■ Long inflation via inflation swaps (receiving actual inflation, paying the fixed leg) ■ In relative terms: overweight inflation-linked bonds vs. nominal bonds.
D 08/07/20- 02/10/21	Real Yield → Nominal Yield ↗ B/E Inflation ↗	As long-term growth expectations stabilized, real yields moved sideways during the next half year (the term premium rose as shorter-term real yields shrank further on near-term growth fears due to renewed lockdowns). Inflation expectations continued to increase alongside nominal yields.	<ul style="list-style-type: none"> ■ Long inflation via inflation swaps (receiving actual inflation, paying the fixed leg) ■ Short nominal government bond futures ■ In relative terms: overweight inflation-linked bonds vs. nominal bonds.
E 02/11/21- 03/19/21	Real Yield ↑ Nominal Yield ↑ B/E Inflation ↗	Both real and nominal yields increased markedly between mid-February and mid-March. A large part of this move was driven by the real term premium while break-even inflation rates rose only slightly.	<ul style="list-style-type: none"> ■ Short nominal government bond futures ■ Curve trade: short 10-year vs. long 5-year (to benefit from a rising term premium) ■ Long inflation via inflation swaps (receiving actual inflation, paying the fixed leg) ■ In relative terms: overweight inflation-linked bonds vs. nominal bonds.
F 03/20/21- 06/11/21	Real Yield ↘ Nominal Yield ↘ B/E Inflation →	Both nominal and real yields receded again (moving largely in parallel) whereas break-even inflation expectations went back to mid-March levels.	<ul style="list-style-type: none"> ■ Long nominal government bonds

Conclusion

Inflation erodes the real value of fixed nominal cash flows and is therefore one of the key risks for which bond holders want to be compensated. All else being equal, passive bond investors' return expectations deteriorate when inflation rises. But active managers can take a more nuanced perspective: bond yield fluctuations result from changes in the different risk premia. With the right toolkit and sufficient agility, fixed income investors have the potential to generate returns from such volatility by gaining selective exposure to the different risk premia.

Understanding the drivers of government bond yields and how to use these tools are critical skills when the inflation outlook is uncertain. They allow active managers to take advantage of both rising and falling inflation expectations. This can be accomplished either via direct investments in inflation or in combination with other risk premia, as part of a holistic approach to duration and yield curve positioning in government bonds. The yield drivers can shift quickly, requiring nimble positioning to generate consistent outperformance potential.

IMPORTANT RISK CONSIDERATIONS

Credit & Interest: Debt securities are subject to various risks, the most prominent of which are credit and interest rate risk. The issuer of a debt security may fail to make interest and/or principal payments. Values of debt securities may rise or fall in response to changes in interest rates, and this risk may be enhanced with longer-term maturities. **U.S. Government Securities:** U.S. government securities may be subject to price fluctuations. An agency may default on an obligation not backed by the United States. Any guarantee on U.S. government securities does not apply to the value of the portfolio's shares. **High Yield-High Risk Fixed Income Securities:** There is a greater level of credit risk and price volatility involved with high yield securities than investment grade securities. **Market Volatility:** Local, regional, or global events such as war, acts of terrorism, the spread of infectious illness or other public health issue, recessions, or other events could have a significant impact on the fund and its investments, including hampering the ability of the fund's portfolio manager(s) to invest the fund's assets as intended.
